## **Optimizing queries**

## alx

## Introduction

A subquery, also known as a **nested query**, is a query embedded within another SQL statement, such as **SELECT**, **WHERE**, **FROM**, **JOIN**, **INSERT**, **UPDATE**, or **DELETE**.

Subqueries enable the **retrieval** of **data** from one or more tables **based** on the results of an **inner** query and offer **alternative options** to JOINS, functions, and window functions.

Subqueries often come at the cost of **lower readability** and **lower performance**, so they should be used with great consideration.

# **Example dataset**

We will be using the following Water\_samples to **describe the purity of water** as a **score from 0 to 100**. The samples have been named, and the analysis type that was used to determine that score. The cost of each type of analysis is provided in the Analysis\_costs table.

## Water\_samples table

Sample_name	Purity	Analysis_type
Alpha	68	Basic
Bravo	75	Advanced
Charlie	52	Basic
Delta	89	Advanced
Echo	92	Basic

## Analysis\_costs table

Analysis_type	Cost
Advanced	1000
Basic	50

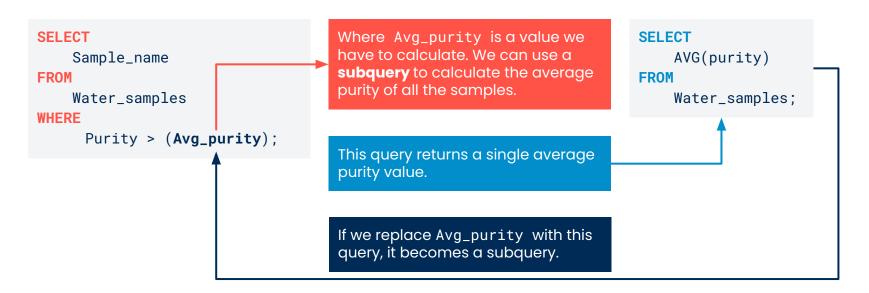

## Sample\_location table

Sample_name	Location	Source
Alpha	Ziwa Maji	Lake
Bravo	Limpopo	River
Charlie	Mji	River
Delta	Nairobi	Тар
Echo	Jangwa	Тар

# What are subqueries?

Suppose we want to retrieve the Sample\_name in the Water\_samples table that has **above-average purity**. To do this, we have to calculate the average purity, then use that value to filter with.

4

# What are subqueries?

When there are **nested queries** present, the **inner** query is executed **first**, **then** the **outer** query is evaluated.

The **inner** query executes first and calculates a **single** average value of 75.2 that is used in the **outer** query as a filter.

```
SELECT
Sample_name,
Purity
FROM
Water_samples
WHERE
Purity > Avg_purity
75.2
```

# Using subqueries

**Subqueries** serve many different purposes and can be used in the SELECT, FROM, WHERE, JOIN, and HAVING clauses.

## Water\_samples table

Sample_name	Purity
Alpha	68
Bravo	75
Charlie	52
Delta	89
Echo	92

A subquery can be used in the WHERE clause to calculate the average purity of all the rows in the Water\_samples table.

Sample_name	Purity
Delta	89
Echo	92

A subquery in the SELECT section of a query always has to return a scalar value.

# SELECT Sample\_name, Purity, (SELECT AVG(Purity) FROM Water\_samples ) AS Avg\_purity FROM Water\_samples;

#### Result set:

Sample_name	Purity	Avg_purity
Alpha	68	75.2
Bravo	75	75.2
Charlie	52	75.2
Delta	89	75.2
Echo	92	75.2

Each **row** in the Avg\_purity column has the **same value** calculated by the subquery.

Most of the results in the following examples can be retrieved with simpler queries, so the aim is to illustrate subqueries that we may encounter in the future.

A **correlated subquery** is a type of SELECT query that uses **values** from the **outer** query. The inner query executes, referencing these value(s), and **returns** the **result** to the outer query. This happens **row by row**.

Suppose we want to calculate the total cost of each sample that was analyzed. We can use a correlated subquery that looks up the cost of the analysis from the Analysis\_costs table for each row.

Begin with a list of samples from the Water\_samples table.

For each sample, look at its Analysis\_type.

Go to the Analysis\_costs table. Find the cost associated with that specific Analysis\_type.

End with a list that shows each sample's name, its Analysis\_type, and the associated cost.

Sample_name	Analysis_type	Cost
Alpha	Basic	70.67
Bravo	Advanced	82
Charlie	Basic	70.67
Delta	Advanced	82
Echo	Basic	70.67

**O1.** For row l, Sample\_name = Alpha and Analysis\_type = 'Basic.' The **subquery then references**Analysis\_type, which is 'Basic' for this row.

Sample_name	Analysis_type	Cost
Alpha	Basic	
Bravo	Advanced	
Charlie	Basic	
Delta	Advanced	
Echo	Basic	

**02.** The **subquery then executes**, using 'Basic' as the condition to filter the Analysis\_costs table on, and returns a single value of 50.

## Subquery result set:

Analysis_type	Cost
Advanced	1000
Basic	50

**03.** Finally, Cost is updated with the subquery result, and the next row is evaluated.

Sample_name	Analysis_type	Cost
Alpha	Basic	50
Bravo	Advanced	
Charlie	Basic	
Delta	Advanced	
Echo	Basic	

**04.** For row 2, Analysis\_type = 'Advanced.' The subquery filters Analysis\_costs using 'Advanced' and returns a value of 1000.

Sample_name	Analysis_type	Cost
Alpha	Basic	50
Bravo	Advanced	1000
Charlie	Basic	
Delta	Advanced	
Echo	Basic	

**05.** The calculation is repeated for each row in the dataset.

Sample_name	Analysis_type	Cost
Alpha	Basic	50
Bravo	Advanced	1000
Charlie	Basic	50
Delta	Advanced	1000
Echo	Basic	50

**Optimizing queries** 

# **Subqueries in SELECT**

This query can also be done using a JOIN statement that is **simpler** to understand. Note how both the WHERE condition and the ON statement refer to the **connection** we would like to "join" on.

## **Subquery**

## JOIN

```
SELECT
    ws_out.Sample_name,
    ws_out.Analysis_type,
    (an_cost.cost) AS Cost
FROM
    Water_samples AS ws_out
JOIN
    Analysis_costs AS an_cost
ON
    an_cost.Analysis_type = ws_out.Analysis_type;
```

# **Subqueries in FROM/JOIN**

Subqueries can be used in FROM and JOIN to create intermediate or **derived tables**, which can be **queried again**. This is particularly useful when we would like to **use aggregated** data along with column data.

Suppose we want to calculate the total cost of all the samples analyzed. We can use the previous query where we calculated the cost and SUM() the column.

#### Previous results set:

Sample_name	Analysis_type	Cost
Alpha	Basic	50
Bravo	Advanced	1000
Charlie	Basic	50
Delta	Advanced	1000
Echo	Basic	50

**Optimizing queries** 

# **Subqueries in FROM/JOIN**

```
SELECT
   SUM(Cost)
FROM
   (previous_query) AS Total_cost;
```

The previous query result can be used as a **derived table**, which the **outer query** uses to **sum** with. If we use a **subquery** in FROM, we **have to alias** the derived table using **AS**.

## Input tables:

Sample _name	Purity	Analysis _type
Alpha	68	Basic
Bravo	75	Advanced
Charlie	52	Basic
Delta	89	Advanced
Echo	92	Basic

Analysis _type	Cost
Advanced	1000
Basic	50

# **Subqueries in FROM/JOIN**

```
SELECT
   SUM(Cost)
FROM
   (SELECT
       ws_out.Sample_name,
       ws_out.Analysis_type,
           (SELECT
               Cost
            FROM
               Analysis_costs
            WHERE
               Analysis_type = ws_out.Analysis_type
               ) AS Cost
    FROM
       Water_samples AS ws_out) AS Total_cost;
```

# Î

Subqueries can, in theory, be nested indefinitely but become **harder to understand** with **each** added **level**.

## Input tables:

Sample _name	Purity	Analysis _type
Alpha	68	Basic
Bravo	75	Advanced
Charlie	52	Basic
Delta	89	Advanced
Echo	92	Basic

Analysis _type	Cost
Advanced	1000
Basic	50

## Derived table:

Sample _name	Analysis _type	Cost
Alpha	Basic	50
Bravo	Advanced	1000
Charlie	Basic	50
Delta	Advanced	1000
Echo	Basic	50

### Final result:

Total_cost	
2150	

# **Subqueries in FROM/JOIN**

Subqueries can add **complexity** to SQL statements, often making them harder to understand. However, **there** are cases where they offer a more concise and efficient solution.

```
SELECT
   SUM(Cost)
FROM
   (SELECT
       ws_out.Sample_name,
       ws_out.Analysis_type,
           (SELECT
               Cost
            FROM
               Analysis_costs
            WHFRF
               Analysis_type = ws_out.Analysis_type
               ) AS Cost
    FROM
       Water_samples AS ws_out) AS Total_cost;
```

With the highlighting removed, it becomes much **harder to understand** what the subquery does, especially compared to a solution that does not use subqueries:

```
SELECT
   SUM(ac.Cost) AS Total_cost
FROM
   Water_samples AS ws_out
INNER JOIN
   Analysis_costs AS an_cost
ON
   ws_out.Analysis_type = an_cost.Analysis_type;
```

# Subqueries in WHERE/HAVING

Subqueries can be used in WHERE and HAVING to enable **customized or advanced filtering** of results.

Suppose we want to retrieve the records in the Water\_samples table that have **above-average purity**.

## Results set:

Sample_name	Purity
Delta	89
Echo	92

The subquery removes all records with Purity < AVG(Purity).

# Subqueries in WHERE/HAVING

Subqueries in WHERE and HAVING can return **scalar values** if used with comparison operators or can return a **single column** of values if used with the IN() operator.

Suppose we want to retrieve the **source types** of samples that have **above-average purity**. We can use the results of the previous query as a list of options in a WHERE... IN clause to select samples that have **above-average purity**.

#### Previous results set:

Sample_name	Purity
Delta	89
Echo	92

## SELECT

Sample\_name,
Location,
Source

#### **FROM**

Sample\_location

## **WHERE**

Sample\_name IN(prev\_query)

## Final results set:

Sample_name	Location	Source
Delta	Nairobi	Тар
Echo	Jangwa	Тар

# **Subqueries in WHERE/HAVING**

# Here's the entire query and the result sets:

## Input tables:

Sample_name	Purity	Analysis _type
Alpha	68	Basic
Bravo	75	Advanced
Charlie	52	Basic
Delta	89	Advanced
Echo	92	Basic

Sample_name	Location	Source
Alpha	Ziwa Maji	Lake
Bravo	Limpopo	River
Charlie	Mji	River
Delta	Nairobi	Тар
Echo	Jangwa	Тар

```
SELECT
   Sample_name,
   Location,
   Source
FROM
   Sample_location
WHERE
   Sample_name IN (
   SELECT
      Sample_name
   FROM
      Water_samples
   WHERE
      Purity > (
      SELECT
         AVG(Purity)
      FROM
         Water_samples)
      );
```

#### Intermediate results:

Avg_purity	
75.2	

Sample_name			
Delta			
Echo			

#### Final result:

Sample_name	Location	Source
Delta	Nairobi	Тар
Echo	Jangwa	Тар
